Development and Validation of Deep Learning Models for Screening Multiple Abnormal Findings in Retinal Fundus Images

Jaemin Son, MSc,[1,*] Joo Young Shin, MD, MSc,[2,*] Hoon Dong Kim, MD, MSc,[3] Kyu-Hwan Jung, PhD,[1] Kyu Hyung Park, MD, PhD,[4] Sang Jun Park, MD, MSc[4]

Purpose: To develop and evaluate deep learning models that screen multiple abnormal findings in retinal fundus images.

Design: Cross-sectional study.

Participants: For the development and testing of deep learning models, 309 786 readings from 103 262 images were used. Two additional external datasets (the Indian Diabetic Retinopathy Image Dataset and e-ophtha) were used for testing. A third external dataset (Messidor) was used for comparison of the models with human experts.

M ...pital Retin... ...eoul Natio... ...ton- woo... ...cular abno... ...with their...

M ...and spec... ...the perfo...

R ...% to 99.9... ...ious findi... ...sted in the Indian Diabetic Retinopathy Image Dataset and e-ophtha dataset were 94.7% to 98.0%. The model demonstrated a performance that rivaled that of human experts, especially in the detection of hemorrhage, hard exudate, membrane, macular hole, myelinated nerve fiber, and glaucomatous disc change.

Conclusions: Our deep learning algorithms with region guidance showed reliable performance for detection of multiple findings in macula-centered retinal fundus images. These interpretable, as well as reliable, classification outputs open the possibility for clinical use as an automated screening system for retinal fundus images. *Ophthalmology 2019;■:1–10 © 2019 by the American Academy of Ophthalmology. Supplemental material available at www.aaojournal.org.

Macula-centered retinal fundus images may be used for screening potential vision-threatening conditions, including diabetic retinopathy (DR),[1–3] age-related macular degeneration (AMD), and glaucoma.[4] To maximize accessibility and mitigate cost, automatic algorithms have been developed in the past decade to streamline the process for the diagnosis of DR[5,6] and glaucoma.[7–9] Recently, deep neural networks[10] have revolutionized the field of medical image analysis, and the diagnoses of DR, AMD, and possible glaucoma with these deep learning algorithms have demonstrated discriminative abilities comparable with those of ophthalmologists.[11–20] However, because a diverse spectrum of abnormal findings and diseases can be found on fundus examination, a deep learning algorithm that identifies multiple disease conditions may be more ideal for clinical application. Also, these deep learning algorithms do not reveal how the decisions are made for the diagnoses, limiting interpretation of the outputs of these algorithms and discouraging potential clinical use. Ophthalmologists usually determine diagnoses in retinal fundus images by observing certain findings (e.g., hemorrhage, exudate, cotton-wool patches, etc.) that are associated commonly with the diagnosis (e.g., DR, glaucoma, etc.). This stepwise process is not embedded explicitly in deep learning algorithms that are trained in an end-to-end manner to generate outputs regarding diagnoses directly from an input image.

Computerized Bone Age Estimation Using Deep Learning–Based Program: Evaluation of the Accuracy and Efficiency

Jeong Rye Kim[1]
Woo Hyun Shim[1]
Hee Mang Yoon[1]
Sang Hyup Hong[1]
Jin Seong Lee[1]
Young Ah Cho[1]
Sangki Kim[2]

OBJECTIVE. The purpose of this study is to evaluate the accuracy and efficiency of a new automatic software system for bone age assessment and to validate its feasibility in clinical practice.

MATERIALS AND METHODS. A Greulich-Pyle method–based deep-learning technique was used to develop the automatic software system for bone age determination. Using this software, bone age was estimated from left-hand radiographs of 200 patients (3–17 years old) using first-rank bone age (software only), computer-assisted bone age (two radiologists with software assistance), and Greulich-Pyle atlas–assisted bone age (two radiologists with

Bone age estimation is crucial for developmental status determinations and ultimate height predictions in the pediatric population, particularly for patients with growth disorders and endocrine abnormalities [1]. Two major left-hand wrist radiograph-based methods for bone age estimation are currently used: the Greulich-Pyle [2] and Tanner-Whitehouse [3] methods. The former is much more frequently used in clinical practice. Greulich-Pyle–based bone age estimation is performed by comparing a patient's left-hand radiograph to standard radiographs in the Greulich-Pyle atlas, which comprises a simple comparison of multiple images, can be repetitive and time consuming and is thus sometimes burdensome to radiologists. Moreover, the accuracy depends on the radiologist's experience and tends to be subjective.

Since 1992, concerns regarding interobserver variability in manual bone age estimation [4] have led to the establishment of several automatic computerized methods for bone age estimation, including computer-assisted skeletal age scores, computer-aided skeletal maturation assessment systems, and BoneXpert (Visiana) [5–14]. BoneXpert was developed according to traditional machine-learning techniques and has been shown to have a good performance for patients of various ethnicities and in various clinical settings [10–14]. The deep-learning technique is an improvement in artificial neural network [15]. An algorithm to program itself by learning from the images given a large dataset of labeled examples, thus removing the need to specify rules [15].

Deep-learning techniques permit higher levels of abstraction and improved predictions from data. Deep-learning techniques

An Algorithm Based on Deep Learning for Predicting In-Hospital Cardiac Arrest

Joon-myoung Kwon, MD;* Youngnam Lee, MS;* Yeha Lee, PhD; Seungwoo Lee, BS; Jinsik Park, MD, PhD

Background—In-hospital cardiac arrest is a major burden to public health, which affects patient safety. Although traditional track-and-trigger systems are used to predict cardiac arrest early, they have limitations, with low sensitivity and high false-alarm rates. We propose a deep learning–based early warning system that shows higher performance than the existing track-and-trigger systems.

Methods and Results—This retrospective cohort study reviewed patients who were admitted to 2 hospitals from June 2010 to July 2017. A total of 52 131 patients were included. Specifically, a recurrent neural network was trained using data from June 2010 to January 2017. The result was tested using the data from February to July 2017. The primary outcome was cardiac arrest, and the secondary outcome was death without attempted resuscitation. As comparative measures, we used the area under the receiver operating characteristic curve (AUROC), the area under the precision–recall curve (AUPRC), and the net reclassification index. Furthermore, we evaluated sensitivity while varying the number of alarms. The deep learning–based early warning system (AUROC:

JAHA Journal of the American Heart Association

In-hospital cardiac arrest is a major burden to public health, which affects patient safety.[1–3] More than a half of cardiac arrests result from respiratory failure or hypovolemic shock, and 80% of patients with cardiac arrest show signs of deterioration in the 8 hours before cardiac arrest.[4–9] However, 209 000 in-hospital cardiac arrests occur in the United States each year, and the survival discharge rate for patients with cardiac arrest is <20% worldwide.[10,11] Rapid response systems (RRSs) have been introduced in many hospitals to detect cardiac arrest using the track-and-trigger system (TTS).[12,13]

Two types of TTS are used in RRSs. For the single-parameter TTS (SPTTS), cardiac arrest is predicted if any single vital sign (eg, heart rate [HR], blood pressure) is out of the normal range.[14] The aggregated weighted TTS calculates a weighted score for each vital sign and then finds patients with cardiac arrest based on the sum of these scores.[15] The modified early warning score (MEWS) is one of the most widely used approaches among all aggregated weighted TTSs (Table 1)[16]; however, traditional TTSs including MEWS have limitations, with low sensitivity or high false-alarm rates.[14,15,17] Sensitivity and false-alarm rate interact: Increased sensitivity creates higher false-alarm rates and vice versa.

Current RRSs suffer from low sensitivity or a high false-alarm rate. An RRS was used for only 30% of patients before unplanned intensive care unit admission and was not used for 22.8% of patients, even if they met the criteria.[18,19]

Corrective/preventive actions from customer feedback

“I’d like to pay per case.”	Provide cloud-based service model
“I like the report, and my patients like report.”	Make better report
“It’s better than me.”	Expand training set, upgrade performance
“It’s not like me.”	Expand training set, upgrade performance
“Why two hands images don’t work?”	Make CAD find one hand

And more importantly…

Quality management activities
Including software version control, training dataset management

VUNO Med® – BoneAge is ACTIVELY, clinically used by ≥ 50 hospitals, for ≥ thousands of children in Korea.

Standalone Package

- Direct sales with own viewer, mainly used in tertiary hospitals
- Hospital-level adoption for newly formed hospitals

Cloud Service

- Easy access
- Pay per diagnosis (First and only in Korea)
- High repeat purchase rate
- Actively using in real world

Integrated Engine

- Integrated with PACS
- SaaS based model for PACS companies
- Research-friendly
